Project Operations

D.1 Introduction

- 4 The Species Conservation Habitat (SCH) ponds are intended to be operated in a manner that would both
- 5 provide a partial in-kind re placement for some of the near-term habitat losses at the Salton Sea (the Se a)
- and answer key question s regarding t he development of shallo w-water habitat as part of a long-term
- 7 restoration program at the Sea. Operations of the Salton Sea SCH Project (Project) co mponents would
- 8 have to balance habitat requirements necess ary to achieve desired objectives against com peting
- 9 constraints such as environmental limitations (ph ysical, water quality, and clim atological conditions);
- 10 compatibility with existing and future adjacent land uses (agricultural fields, geothermal development,
- and other habitat projects at the Sonny Bono Salton Sea National Wildlife Refuge); and habitat values (at
- the refuge); and consistency with the applicable requirements of the Imperial Irrigation District (IID)
- Habitat Conservation Plan/Natural Communities C onservation Plan. Decisions necessary to strike this
- balance and meet the objectives would be made within an adaptive management framework.
- 15 This appendix provides a conceptual overview of the range of operations that could be used to provide
- suitable habitat (for species dependent on the Salton Sea) and to test different operational scenarios as part
- of the "proof-of-concept" aspect of the SCH Project. Key indicators of physical, chemical, and biological
- attributes of that habitat would be monitored to determine the effects of different operational scenarios,
- and any adjust ments would be im plemented as nee ded in accordance with the SCH Monitoring and
- 20 Adaptive Management Framework, as described in Appendix E.

21 D.2 Key Project Components

- 22 The general facilities necessary for each alternative in clude river water diversion, sedimentation basin,
- saline water diversion, SCH ponds, in-pond habitat features, and an agricultural drain interception ditch.

24 D.2.1 River Water Diversion

- 25 River water would be diverted for the use of producing shall ow-water aquatic habitat in one of two
- 26 manners. For Alternatives 1 and 4, river water would be diverted via a la teral weir placed on the edge of
- 27 the river channel. The diversion weir would be located upstream of the SCH p onds to provide sufficient
- 28 hydraulic head to convey the water to the SCH pond s with gravity. For Alternatives 2, 3, 5, and 6, river
- water would be diverted via electrically driven pumps located adjacent to the SCH ponds.

30 D.2.2 Sedimentation Basin

- Waters in the New and Alamo rivers contain suspended sediment that would need to be removed prior to
- 32 conveyance and delivery to the SCH habitat ponds. The concentration of the suspended sediment in the
- rivers is recently reported at about 219 milligrams per liter (mg/L) for the New River and 280 m g/L for
- 34 the Alam o River. The water diverted to the SCH ponds from the rivers would have to go through a
- 35 sedimentation basin to rem ove the sediment load before the water is release d to the SCH ponds. For
- 36 alternatives u sing a gravity diversion, the sedi mentation basin would be locat ed upstream of the SCH
- ponds near the point of di version. For alternatives using the pumped diversion, the sedimentation basin
- would be located within the SCH pond footprint.
- 39 The sedimentation basin would be operated to hold the water just long enough f or the sediment to settle
- 40 out. The settling time is a function of the size of the particles suspended in the water column.

- 1 Sedimentation basins elsewhere in the Imperial Valley store water for about 5 day s. Routine operations
- would include the removal and disposal of the sed iments collected in the sedimentation basin. The
- 3 frequency of these actions and amount of material to be removed would be determined once an alternative
- 4 were selected for design and could be modified during the life of the SCH Project as a result of sediment
- 5 control measures being independent ly im plemented as part of the Clean Water Act Section 303(d)
- 6 requirements (Total Maximum Daily Loads).

7 D.2.3 Saline Water Diversion

- 8 Saline water would be diverted by electrically driven pumps placed on a struc ture in or adjacent to the
- 9 Salton Sea to produce the desired salinity in the SCH ponds. The water must be pumped (lifted) because
- 10 the Sea's elevation Sea is less th an the desired p ond elevation of -228 feet mean sea level (msl).
- 11 Currently, the water would have to be lifted about 4 feet in elevation from the Sea to the SCH ponds. As
- the Sea's elevation declines over time, the height that the saline water would have to be lifted would
- increase, along with the distance that the water had to be conveyed to reach the ponds.

14 D.2.4 SCH Pond Berms

- 15 The SCH point complex would be formed by constructing low height (up to approximately 8-foot-high)
- berms to contain water and separate the SCH ponds from the remainder of the Salton Sea and its recently
- 17 exposed playa. Internal berms would segment the SCH ponds into experimental units.
- 18 The SCH ponds would be constructed prim arily on recently exposed pla ya following the existing
- 19 topography (ground-surface contours) where possible. The ground surface within the SCH ponds would
- be excavated (with a balance between cut and fill) to acquire material to build the berm's and habitat
- 21 islands. The borrow areas for the berms would generally form adjacent channels, swale channels, and
- shallow excavations. The maxim um water surface elevation would be -228 feet msl. Pond depth would
- range from near zero toward the shoreline (-228 msl) to 6 feet at the exterior b erm. Maximum depth in
- excavated areas would be up to 10 feet. Outflow stru ctures would be constructed in the outer berms, and
- 25 maximum outflow from the SCH pond complex to the Salton Sea would total approximately 130 cubic
- 26 feet per second.

39

- 27 Berms would be maintained to repa ir dam age due to structural failu res, differential settli ng, surface
- erosion, access, and water management functions. Ber ms may require future s trengthening by others to
- accommodate other compatible land uses (e.g., geothermal development).

30 D.2.5 In-Pond Habitat Features

- 31 Several constructed bird and fish habitat structures would be included in the SCH ponds, such as swales,
- 32 holes, and habitat islands. Swales are 2-foot or deeper channels within the pond units that would be
- constructed with scr apers and excavat ors. They ultimately would serve as habitat feature s to incre ase
- 34 aquatic habitat heterogeneity, con nect shallow and deep areas of a pond unit, and provide deeper refugia
- near shallow areas. Each S CH pond would include several islands for bird habitat: one to three nesting
- 36 islands (suitable for tern species) and three to six smaller roosting islands (suitable for cor morants and
- pelicans). The overall SCH pond complex could also include one or more large (2- to 10-acre) islands that
- have rocky and sandy substrate (suitable for cormorant nesting).

D.2.6 Agricultural Drain Interception Ditch

- Water from a djacent agricultural drains that currently flows (or is pum ped) directly into the Salton Sea
- 41 would be rerouted around the SCH ponds. The inter ception ditch would allow for the continuati on
- 42 connection of these drains to the Salton Sea and not disturb the flow of agricultural drainwa ter from the

- adjacent fields. IID would maintain operational control of these drains and continue to provide all
- 2 maintenance activities necessary on these drains.
- 3 D.3 Operational Variables and Range
- 4 D.3.1 Habitat Requirements and Operational Constraints
- 5 SCH ponds are intended to:
- Provide habitat suitable for production of fish dependent on the Salton Sea. Likely fish candidates are one or more varieties of tilapia, which are an important forage species for fish-eating birds. Other fishes that could become established in the SCH ponds include desert pupfish (*Cyprinodon*
- 9 macularius), sailfin mollies (*Poecilia latipinna*), mosquitofish (*Gambusia affinis*), and threadfin shad (*Dorosoma petenense*).
- Provide habitat suitable to support fish-eating birds and other birds dependent on the Salton Sea.
- Foraging habitat would be a key attribute, but other features to meet habitat needs for nesting and resting would also be included.
- SCH pond o perations would attempt to meet Project goals and objectives given certain constraints of
- physical conditions, water qualit y, and climate. The general characteristics of the aquatic habitat that
- would likely be present for fish include:
- Highly eutrophic, shallow-water ponds that would be highly turbid in spring through fall.
- Low temperatures below 50 degrees Fahrenheit (°F) (10 degrees Celcius [°C]) during short periods of the winter and high temperatures in the low–to mid 90s °F (low 30s °C) in the late spring through early fall.
- Dissolved oxygen (DO) concentrations ranging from zero mg/L at the mudline to super-saturated during daylight hours in spring to fall.
- SCH Project operations would be constrained by the physical characteristics of the ponds (e.g., depth,
- area, and bot tom profile), but certain w ater quality conditions could be modified, within some range of
- conditions, as needed, by adjusting the limited operational controls to create more desirable habitat
- 26 conditions in the ponds. The primary operational variables that could be controlled are:
- Salinity of the water within the ponds;
- Volume of water in the ponds;
- Residence time of the water in the ponds;
- 30 Pond depth;
- Fish species stocked in the ponds; and
- Physical cover elements.
- 33 Depending on the specific alternative and p ond design selected, the habitat would be composed of a few
- 34 to several individual ponds. This design would allow the operators to try different combinations of
- storage, salinity, and residence times to investigate how these factors could be adjusted to provide the best
- 36 conditions for fish and birds. Di fferent operational scenarios would be tested during the proof-of-concept
- phase, the first 10 years of Project oper ation (to approximately 2025). After the proof-of-concept phase,

APPENDIX D PROJECT OPERATIONS

- 1 pond variables would be managed to produce the best habitat for fish and wildlife dependent on the
- 2 Salton Sea.
- 3 The following discussion is based on the construction and operation of approximately 2,400 acres of
- 4 habitat, but the acreage could be less or m ore depending on the alternative select ed and the funding
- 5 available for Project construction.

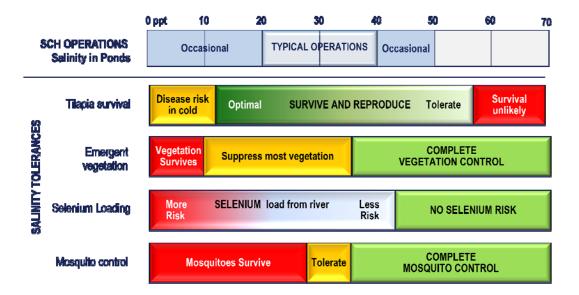

6 D.3.2 Salinity of Stored Water

- 7 The SCH ponds would typically be operated within the range of 20 to 40 parts per thousand (ppt) salinity.
- 8 Water from the Alamo River or New River (salinity approximately 2 ppt) would be blended with water
- 9 from the Sal ton Sea (current ¹ salinity approximately 53 ppt) t o produce the desired pond salinity.
- Blending the river water and seawater in different amounts would allow for a range of salinities to be used
- 11 in the ponds.²
- Different ponds could be operated under different salinities to test which salinity regime results in the best
- 13 combination, or balance, of invertebrate and fish productivity, bird use, seasonal fish survival, and
- exposure to selenium (Figure D-1). For example, cold tolerance by tilapia is better at lower salinities (20
- ppt) than at higher salinities (60 ppt) (Lorenzi and S chlenk, in preparation), but seleniu m loading to the
- pond is increased (more river water eq uals lower salin ity but hi gher inputs of water-borne seleniu m)
- 17 (Appendix I, Selenium Management Strategies). Salinity in the ponds could also be increas ed as needed
- 18 to contro I mosquito po pulations (App endix F, Mo squito Co ntrol Plan), co ntrol em ergent vegetation
- 19 growth (Tabl e D-1), and limit the development of aquatic habitat that woul d support fre shwater fish
- 20 known to be predators of desert pupfish.
- During the proof-of-concept phase, sali nities would be typically managed between 20 to 40 ppt. This
- range is generally sufficient to control many of the negative factors listed above and within the range to
- be tolerated by the fish's pecies expected to be u sed in the SCH ponds. Pond salinity may be allowed to
- exceed this general range (from undiluted river water [2 ppt] up to 50 ppt) in the course of balancing
- evaporation and water pum ping, or if deem ed appropriate to test specific fish management or habitat
- value hy potheses. For exam ple, it may be desirable to operate each pond at a different salinit y (e.g.,
- 27 undiluted river water, 20 ppt, and 40 ppt) and m onitor biological outcomes and long-term operational
- feasibility. SCH ponds would not be operated with hy persaline conditions (greater than 50 ppt) because
- 29 they would result in decreased viability of the desired aquatic habitat.

⁻

¹ The salinity in the Salton Sea is expected to increase in the future, with salinity exceeding 100,000 ppt by 2030 (DWR and DFG 2007).

² Evapoconcentration, increasing the salinity through the evaporation process, was simulated in the water quality modeling for this Project and found to be ineffective in achieving the desired salinity range in a short period of time.

Figure D-1 Operational Range of Salinities and Biological Constraints

Table D-1 Sa	alinity Tolerances of L	ocal Plant Sp	ecies	
Species	Habitat	Typical Salinity Preference	Widest Salinity Tolerated	Comments and Sources
California Bulrush (<i>Schoenoplectus</i> <i>californicus</i>)	Widespread in fresh and intermediate marsh zone	0-3.5 ppt	Approximately 10 ppt or greater will control populations	Stutzenbaker 1999 Prolonged exposure to extreme conditions (15-20 ppt) exceeds the typical salinity tolerance and populations decline (Louisiana Coastal Wetlands Conservation and Restoration Task Force 2002)
American Bulrush (Scirpus americanus) Olney's three-square bulrush (Schoenoplectus americanus)	Fresh to intermediate marshes	0-3.5 ppt	50% reduction at 4 ppt and no germination above 13 ppt	Stutzenbaker 1999; Uchytil 1992 Management and maintenance depends primarily on maintenance of water levels and secondarily on salinity levels (Uchytil 1992)
Saltmarsh Bulrush (<i>Scirpus maritimus</i> or <i>Scirpus robustus</i>)	Intermediate to brackish marshes, often on soils subject to tidal influence	3.5-10 ppt	Has been found in hypersaline lakes (-60 ppt) Germination reduced 50% at salinity = 9 ppt. No germination at salinity = 21 ppt.	Stutzenbaker 1999; International Lake Environment Committee 1998; Snyder 1991
Broad Leaf Cattail (<i>Typha latifolia</i>)	Freshwater aquatic normally, but also found in intermediate marshes	0-0.5 ppt	Found in intermediate marshes with salinity up to 3.5 ppt In marshes of southeastern Louisiana, occurred at salt levels up to 1.13%	Stutzenbaker 1999
Narrow Leaf Cattail (<i>Typha angustifolia</i>)	Freshwater aquatic normally, but also found in intermediate marshes; coastal	0-0.5 ppt	15-30 ppt	Stutzenbaker1999; Reed et al.1995
Southern Cattail (<i>Typha domingensis</i>)	Wetlands ranging from fresh to brackish	0-10 ppt	75% mortality occurred at 15 ppt	Stutzenbaker 1999; Glenn et al. 1995

D.3.3 Volume of Water in Storage

- Storage is the amount of water contained in the SCH ponds at a given time. The volume that could be stored would depend upon the size of the ponds, which varies by alternative. The storage would also be
- controlled by changing the inflow and outflow to the SCH ponds. A pond could be operated at a constant
- storage or vary ing storage, depending on the proof-o f-concept testing. Reasons for vary ing storage (and
- hence the maximum depth and inundated area) inclu de responding to water quality conditions, desire to
- 8 create different habitat conditions in the pond (e.g., shallow-water hab itat), vector control, or pond
- 9 maintenance.

1 2

3

- Water quality m odeling performed for the SCH Project has shown that DO or tem perature conditions
- respond to several operational parameters, including the depth of the water in a pond and pond shape (the
- 12 relationship between water depth and surface ar ea). Therefore, changing storage in the pond can alter
- these conditions by changing the amount of shallow- and deepwater habitat.

- The storage could be operated at any amount from empty (e.g., for emergency maintenance) to full with a
- 2 maximum depth of approximately 6 feet at the term in al berm. Should the average depth of the pond be 3
- feet, the storage at full depth would be approximately 7,200 acre-feet for a con structed pond complex of
- 4 2,400 acres. Operators would determine the appropriate depth and manage the total storage in the p ond to
- 5 meet that depth.

6 D.3.4 Residence Time

- 7 Residence time is a measure of the time it would take the average unit of water volume to pass through
- 8 the SCH ponds (or loss to evaporation). The residence time defines the amount of water diverted from the
- 9 river and the Sea and in turn controls the diversion facilities, Project energy use, and cost. Residence time
- may be an important parameter for the control of habitat conditions in the SCH operations.
- SCH pond residence time would be altered as a result of other operations of the SCH ponds or could be an
- 12 experimental variable for operational testing. Residence time may vary in response to climatic conditions
- 13 (including temperature, wind frequency, direction and speed, and solar illumination) or may be modified
- 14 to test various hypotheses regarding the habitat value during differing climatic conditions and to control
- anticipated negative conditions. These negative conditions would include the increased probability of
- depleted DO concentration (anoxia) in portions of the water column or pond areas.
- 17 During the Project's proof-of-concept phase, pond r esidence time would be managed to test the
- hypotheses developed through the use of the adaptive management process (see Appendix E). Based on
- preliminary water quality modeling results (see Appendix J, Summary of Special Studies Supporting the
- 20 EIS/EIR Impact Analysis), it is anticipated that r esidence times could vary from a couple of weeks (2
- 21 weeks) to several months (32 weeks). This range is generally sufficient to support the proof-of-concept
- 22 testing while allowing for the control of potential negative factors and the production of the desired
- habitat.

24 D.3.5 Pond Depth

- 25 The maximum and average depth of water in the SCH ponds would be varied to test various hy potheses
- 26 regarding habitat value during differing climatic conditions and to control anticipated negative conditions
- 27 listed above for residence time. Depth also could be controlled to manage predation on the fish in the
- ponds. Different ponds could be operate d at different depths, and pond de pth could be changed to test
- different scenarios. A range of depths would be created through excavation of material used for berms.
- The depth (and pond area) could also be changed by varying the amount of water stored in a pond during
- 31 the year.
- 32 During the Project's proof-of-concept phase, pond de pth would be managed to test the hy potheses
- developed through the use of the adaptive management process (see Appendix F). Based on preliminary
- water quality m odeling results (see Ap pendix J), it is anticipated that the m aximum pond depth at t he
- edge of the berms would be 6 feet. Pond depth may be managed outside this general range to test specific
- 36 fish management or habitat value hypotheses. Ponds may need to be drained or the elevation lowered for r
- 37 emergency maintenance or to cont rol aquatic conditions, bu t this dr ainage would not be a routine
- 38 occurrence.

39 D.3.6 Fish Stocking in Ponds

40 Fish Species Selection

- The SCH po nds would be designed to support fish to serve as prey for pis civorous birds. Pro mising
- 42 candidate species must be able to forage, grow, and reproduce in fluctuating salinities using the soft, fine-

- 1 grained sediment that would naturally form the p ond substrate. Fish t hat have evolved to deal with
- 2 environmental fluctuations would be better able to th rive in SCH ponds than those whose physiology is
- less plastic when dealing with environmental extremes. 3
- 4 A number of species present in ri verine or estuarine ha bitats of Southern California and Baja California,
- 5 Mexico, could be suitable candidates for a productive SCH fish community (DFG 2011). The main
- 6 attributes considered were foraging suitability for a wide range of piscivorous birds (e.g., no "bottom-
- 7 hugging" flatfish that would be inaccessible to most birds), resistance to perturbation (e.g., tolerates wide
- 8 fluctuations in tem perature, DO, salinity), high productivity, and sustainability. These att ributes were
- 9 weighed against potential risk to desert pupfish, pot ential risk for spread to new habitats not current ly
- 10 occupied, and difficulty or expense in obtaining or producing sufficient numbers for stocking. F or the
- 11 Project's initial establish ment, however, only those species currently inhabiting the Salton Sea and its
- 12 connected waters would be considered for use. Desert pupfish, a federally protected species, are present
- around the Salton Sea and would be included in the SCH ponds. Selecting only fish species that currently 13
- 14 reside at the Sea would avoid any new impacts beyond what the Salton Sea desert pupilish population is
- currently exposed. 15
- Therefore, the fish assemblage propos ed for initia l deliberate in troduction into the SCH p onds would 16
- include one or more forms of tilapia and possibly threadfin shad, as well as desert pupfish, sailfin molly, 17
- 18 and mosquitofish. Stocking more than one fish species in the ponds would provide some redundancy and
- 19 improve sustainability of the fish community. If these initial species do not meet the Project objectives,
- 20 other candidate species evaluated by DFG (DFG 2011) would be considered.

Tilapia

- 22 Tilapia satisfy the entire suite of attributes sought in a candidate species, more than any other single
- species being considered for the SCH Project (DFG 2011). This family of fishes has wide t olerances for 23
- 24 water quality conditions, flexible diet including algae and inverte brates, high fecundity, and distribution
- 25 throughout the water column. Furthermore, they could also support sport fishing. This species is highly
- 26 tolerant of a wide range of salinities, including high salinities, as demonstrated by their current dominance
- 27 in the hypersaline Salton Sea. Juvenile Mozambique hybrids can be slowly acclimated up to 95 grams per
- 28 liter and survive at least for 5 days if the tem perature is kept c onstant at 73 to 77 °F (2 3 to 25 °C)
- 29 (Sardella et al. 2004a). Til apia are less capable of de aling with high salinity under extreme t emperatures
- 30 (Sardella et al. 2004b). The preferred temperature range for optimum tilapia growth is 82° to 86°F (28 t o
- 31 30°C). Growth diminishes significantly at temperatures below 68°F (20°C) and death would occur below
- 32 50°F (10°C) (Rakocy and McGint y 1998). At tem peratures b elow 54°F (12°C), tilapi a are more
- 33 vulnerable to infections by bacteria, fungi, and parasites. The tem perature regime in the SCH ponds
- 34 would be expected to be more extreme than that of the current lake (DWR and DFG 20 07). Models of
- 35 water temperatures for the SCH ponds predict temperatures below the lethal thr eshhold for Mozambique
- 36 hybrid tilapia (Appendix J).
- 37 Tilapia are remarkably tolerant of low DO concentrations, considerably below tolerance limits for most
- 38 fish. Tilapia can thrive at DO concentrations of 2 mg/L, can survive extended periods of 1 mg/L, and can
- 39 tolerate routine dawn DO concentrations of 1 ess than 0.3 m g/L (Popma and Masser 1999). In low DO
- 40 conditions, fi sh frequently are found near the surface ta king in water in the thin surficia 1 lay er t hat
- 41 remains somewhat oxygenated (personal communication, K. Fitzsimmons 2010). Such behavioral coping
- 42 responses could increase the vulnerability of fish to bird predation near the surface.
- 43 Their main drawback, other than potential competition with desert pupfish, is whether they could handle
- the lowest water tem peratures predicted for SCH ponds. Stocki ng different tilapia species or strains 44
- (individually or in combination) among the SCH poinds could test which species is most sustainable and 45

- 1 resilient, and could enhance st ability of the fishery resource in the ponds in the face of seasonal and
- 2 annual fluctuations in water quality parameters. The three tilapia species under consideration for stocking
- 3 in the SCH ponds include the following:
- 4 California Mozambique Hybrid Tilapia California Mozam bique hy brid tilapia (" Mozambique
- 5 tilapia") are a hybrid of *Oreochromis mossambicus* and *O. urolepis hornorum*. This speci es is currently
- 6 the dominant species in the Salton Sea and is widely u sed in aqua culture including at fish far ms in the
- 7 Salton Sea watershed. Advantages of this species ar e its demonstrated ability to survive, thrive, and
- 8 achieve high productivit y in hy persaline conditions, as well as its presu med importance as a suitable
- 9 forage fish for all piscivorous birds at the Salton S ea. The risk from using Mozambique tilapia as the sole
- forage species is the pote intial for population crashes, as se en with the massive fish die -offs at the
- beginning of the decade. The proposed SCH opera tions would be designe d to keep w ater quality
- 12 conditions within known tolerances and, therefore, population fluctuations may be dampened.
- 13 **Blue Tilapia** Blue tilapia (*Oreochromis aureus*) have a lower tolerance for salinity, but handle colder
- temperatures than the othe r two tilapia (Popm a and Masser 1999). Tilapia resem bling blue tilapia are
- currently only present in the New and Alamo rivers. The genetic makeup of this tilapia assemblage is
- uncertain, but likely includes O. aureus and possibly Mozam bique tilapia genetic material given the
- 17 checkered h istory of tilapia introductions an d movements in souther n California (personal
- 18 communication, K. Fitzsimmons 2010).
- 19 **Redbelly Tilapia** Redbelly tilapia (*Tilapia zillii*) were once the dominant tilapia species in the Salton
- Sea, when salinit y was lower. Although the y were replaced by the Mozam bique tilapia, they are still
- 21 thriving in some of the agricultural drains. The difference in their tolerance to salinity and temperature, as
- 22 well as a different breed ing strategy, may provi de plasticity in response to perturbation n for a fish
- community that contains both species.
- 24 The relative tolerances of these species to combinations of salinities (20 ppt, 45 ppt, and 60 ppt) and
- 25 temperatures (cold 11-16°C [52-61 °F]), warm 23-28°C [73-82 °F], and hot 33-38°C [91-100°F]) were
- tested experimentally (Lorenzi and Schlenk, in preparation). The tested fish included Mozambique tilapia
- 27 (two strains: wild fish from Salton Sea and an aquaculture strain from a local fish farm), fish from a blue
- 28 tilapia assemblage in the New River, and redbelly tilapia from the New River. The best survival at cold
- 29 temperatures was observed with the wild Mozam bique tilap ia, while the aquacultural strain of
- 30 Mozambique tilapia was the best performer overal 1 for all sali nities at warm tem peratures. The blue
- 31 tilapia strain surprisingly did not have better survival than Mozam bique tilapia in cold conditions.
- Redbelly tilapia results were equivocal, due to other sources of mortality in captivity. While most strains
- and species had moderately good sur vival in 45 ppt and 60 ppt conditions at warm temperatures, all
- species showed poor survival in hot high-salinity (60 ppt) conditions.

Desert Pupfish

- Desert pupfish are listed as an endangered species un der both Federal and California Endangered Species
- 37 Acts. They currently inhabit the agricultural drains and creeks that feed into the Salton Sea, shallow areas
- of the Sea itself, and numerous cr eated refuge habitats. A stu dy of IID agricultural drains found a n
- 39 abundance of desert pupfish positively correlated w ith west ern mosquitofish, salfin molly, and
- 40 Mozambique hy brid tilapi a (Martin and Saiki 2005). Desert pupfish are observed most frequently in
- 41 shallow water less than ab out 1 foot (30 centi meters) deep with v elocities less than about 1 foot/second
- 42 (Black 1980). They are capable of moving freely between the relatively fresh water in the agricultural
- drains and the highly saline environment in the Salton Sea (DWR and DFG 2007).

- 1 Desert pupish are very tolerant of extreme water quality conditions, and have been held in the laboratory
- 2 in water with salinit y greater than 98 ppt (Barlow 1958, as cited in Moyle 2002). The ability of desert
- 3 pupfish to tolerate high salinity, high pH, and low DO contributes to their ability to persist at the Salton
- 4 Sea. Moyle (2002) summarized the life histor y of desert pupfish as follows, with additional information
- 5 as noted. This species can tolerate salinities ranging from freshwater to considerably greater than seawater
- 6 (up to 68 ppt in the wild), DO fro m saturation to as low as 0.1 to 0.4 m g/L (parts per million), and
- 7 temperatures from 39.9°F (4.4°C) in winter (Schoenherr 1990) to 108.3°F (42.4°C) in summer (Carveth et
- 8 al. 200 6). Individuals can survive daily temperature fluctuations of up to 78.8°F (26°C) and salinit
- 9 changes of 10 to 15 ppt. Larvae have a higher salinity tolerance (up to 90 ppt) than do adults (68 ppt) and
- 10 can withstand sudden salinity changes of up to 35 ppt.
- 11 Under current conditions at the Salton Sea, individu al desert pupfish inhabiting creeks and drains that
- 12 flow into t he Sea are presumed to move along the Sea's margins and among drains. This movement,
- which provi des the opportunit y for genetic exch ange am ong desert pupfish, reduces the potentia
- deleterious effects of isolation of individual populations. It also provides the opportunity to recolonize
- these same areas in the event a local population is extirpated (DWR and DFG 2007). Therefore, the SCH
- 16 Project design would include features to maintain connectivity among populations.
- Desert pupfi sh would likely thrive at the SCH ponds, as seen at the Bure au of Reclamation/U.S.
- Geological Survey Saline Habitat Ponds (Miles et al. 2009). The ponds that had pupfish were mostly less
- than 1 meter deep and had salinities ranging from 12 to 70 ppt (Miles et al. 2009). Pupfish were the most
- abundant fish in the Saline Habita t Ponds; over one million were captured when the ponds were drained
- 21 in late 2010 (personal communication, J. Crayon 2010).

22 Sailfin Molly and Mosquitofish

- 23 Sailfin m ollies and mosquitofish are sy mpatric with desert pupfish in the Salton Sink. Due to their
- presence in the Colorado River, they also occupy much of the agricultural water supply and drainage
- 25 systems around the Salton Sea. Like desert pupfish, they demonstrate plasticity in their diet, and tolerance
- of high water temperature, high salinity, and low oxygen levels. They inhabit the shallow edges of water
- bodies, usually less than 2 feet deep. As livebear ers, they require no special substrate or structure for
- 28 reproduction.
- 29 Desert pupfish, sailfin m ollies, and m osquitofish overlap considerably in t heir trophic roles where they
- 30 co-exist in the Salton Sink. They would provide di versity and a degree of redu ndancy in the SCH fish
- 31 community, which could buffer the effects of perturbation in a dynamic system. Birds that forage for
- 32 small fi sh would prey on all three species; however, surface gleaners and skimmers would find sailfin
- mollies and mosquitofish more accessible, since these fishes are usually active higher in the water column
- than are desert pupfish.

35 Threadfin Shad

- 36 Threadfin shad form schools near the surface in open water. They can live in seawater but do not
- 37 reproduce at that salinity. Spawning takes place in open water near floating or partially submerged objects
- 38 to which the fertilized eggs stick. The eadfin shad feed heavily on larger zooplankton and can greatly
- reduce the abundance of these organisms (Moyle 2002).

40 Filling and Stocking of SCH Ponds

- 41 The SCH ponds would be stocked with fish species currently in the Salton Sea Basin and captured from
- 42 local drainages. The initial SCH aquatic community would be comprised of four primary types of fish:
- 43 tilapia, sailfin molly, mosquitofish, and desert pupfish. Unintentional invasion of other fish from the river

- waters, such as common carp (*Cyprinus carpio*), various Centrarchid species, red shiners (*Cyprinella*
- 2 lutrensis), and threadfin s had, may also occur. All but the shad would be unable to survive in water s
- 3 above 20 ppt salinity.
- 4 Following construction, t he SCH ponds would be f illed with water for the first tim e and allowed to
- 5 "season" for a period of several wee ks while undergoing various stages of che mical and biological
- 6 succession. Water chemi stry would f luctuate as compounds leach from the newly wetted soils and
- 7 microbial communities are initiated. Once phyto- and zooplankton are established and salinity exceeds 20
- 8 ppt, fish could be introduced, starting with sailfin mollies and mosquitofish.
- 9 The first fishes introduced would likely be small species. Sailfin mollies are ubiquitous in the Salton Sea
- and the agricultural drains surrounding it. They could be easily trapped/and or seined for st ocking into
- 11 SCH ponds. The most productive collection of sailfin mollies would take place in the spring, when the
- 12 young-of-the-year would still have an approximately 1:1 sex ratio and have not yet been exhausted by the
- energetic costs of reproduction. Mosquitofish are nume rous in the agricultural drains at the Salton Sea's
- southern end . The y also could be easily trapped a nd/or seined for stocking , or alternately could be
- obtained from aquaculture or vector control agen cies. Pupfish would be trapped and/or seined from
- several natural localities and created refuges to insure a good representation of available genetic diversity.
- 17 Several species and strains of tilapia are present in the waters of the Salton Sea drainag e, and each
- 18 requires a different approach for securing sufficiently large numbers of founders. Mozambique hybrid
- 19 tilapia are currently abundant in the Sal ton Sea and large numbers could easily be captured for stocking
- into SCH ponds. However, their long-t erm availability is tenuous with the increasing salinity in the Sea.
- 21 The same fish is available from local aquacultural facilities, but may not perform as well as wild caught
- fish, given the selection pressure on the wild population that would likely result in greater tolerance of the
- Sea's salinity and temperature range (Lorenzi and Schlenk, in preparation). Redbelly tilapia are abundant
- in drains at the Sea's northern end, particularly those filled by tilewater. These populations should persist,
- due to the consistency of water quality in those drains, and fish would be available for seining/trapping
- for SCH ponds in the future. Finally, tilapia resembling blue tilapia are present in the rivers, agricultural
- drains, and Brawley Wetlands.
- 28 The release of tilapia into SCH ponds should only take place after phy toplankton and zoopl ankton are
- 29 established. If stocks were from freshwater habitats or held in fre shwater while captive, they would be
- first acclimated to the salinity in the ponds. This acclimation could be done under captive maintenance, or
- 31 by sequestering in a small part of t he ponds and allowing the s alinity to gradually rise to pond levels
- before releasing fish into the larger habitat.

Fish Rearing

- Due to ever-i ncreasing salinity and degraded wat er quality in the Salton Sea, the Moza mbique hy brid
- 35 tilapia population in the Sea may have declined seriously by the time of construction of the SCH ponds. If
- 36 so, extremely intense predation pressure on the fish initially stocked in the ponds may occur. A supply of
- fish would be needed for initial stocking of the SC H ponds and possible restocking if severe fish die-offs
- occur. It would be important to stock fi sh in sufficient numbers to start a sustainable population in the
- face of predation. Securing an adequate number of fish for stocking may require producing a generation
- 40 in captivity from captured wild fish. Tilapia could be collected now from local sources while wild stocks
- 41 remain and held for captive propagation at one or more of the private licensed aquaculture facilities in the
- 42 area (within 15 m iles of all alternative sites). Several tr ips (fewer than ten) by small (½ to 1 ton) trucks
- 43 would be required if cultured fish are to be delivered from an aquaculture facility to SCH ponds.

1 Physical Cover

- 2 Heterogeneity in physical habitat structure could be manipulated in the SCH poinds to enhance cover and
- 3 refugia for fish from pre dators and possible therma 1 fluctuations. Refugia from predators would be
- 4 necessary to allow a sustainable population of fish t o persist in the face of ex pected heavy predation by
- 5 piscivorous birds, especially when fishery resources in the Salton Sea decline and disappear. Refugia or
- 6 cover could be provided by deeper waters or phy sical structural complexity. Types of cover elements
- 7 considered include:
- 8 Swales and Channels Having water deeper than 3 feet in proximity to shallower areas would allow fish
- 9 to disperse into areas where they would be m ore dispersed and/or less visible due to turbidity. These
- 10 constructed regions of greater depth would provide this element.
- 11 **Submerged Aquatic Vegetation** Vegetation coul d also provid e cover fro m predators, especially for
- small fish. Widgeon gra ss (*Ruppia* spp.) is expected to become established in the SCH ponds. This
- vegetation would likely enhance food supplies by providing more microhabitat structure to support
- invertebrate diversity and productivity. Widgeon grass establishes from seed and needs sufficient light for
- photosynthesis to reach the pond bottom. Given the projected turbidity, it would be limited to shallow
- areas of SCH ponds.
- 17 **Floating Islands** These artificial str uctures could be used to provide visual cover and shading for
- 18 potential thermal refugia. Floating islands could be deployed in different areas, and would likely be most
- 19 useful in shallower are as where other cover is limited. More information would be necess ary to evaluate
- 20 the applicability and feasibility of floating islands.
- 21 While many of these components would be considered part of the initial pond construction, placement
- and size of floating islands could be manipulated to test habitat function. Monitoring of their effectiveness
- would be a component of the adaptive management approach for the SCH design and operations.

24 D.4 Possible Operational Scenarios

- 25 Possible operational scenarios are shown in Tables D-2 to D-7. These scenarios are meant to test different
- 26 concepts for creating sustainable saline habitat for fish and wildlife that minimizes risks of impacts such
- as fish die-offs, ecotoxicity from sel enium, and diseases vector s. Upper and lower extre mes of the
- operational range would be tested to detect any effect of that variable on Project performance. Operational
- 29 values for each variable could be held constant over time or could be adjusted sea sonally according to
- 30 expected outcomes.
- The ranges of operational variables to be tested are as follows:
- 32 **Salinity** 20-40 ppt.
- 33 **Storage** Approxim ately 80 to 1 00 percent of cap acity (the volume would depend on the actual
- 34 alternative selected and am ount of ponds constructed). For example, for a constructed pond complex of
- 2,400 acres, storage could range from 6,000 to 7,200 acre-feet, assuming an average depth of 3 feet deep
- 36 over 2,400 acres).
- 37 **Residence Time** 2 to 32 weeks. This range reflects rate of inflow and outflow.
- 38 **Fish Species** Fishes considered for initial introduction into S CH ponds would include one or more
- forms of tilapia, threadfin shad, desert pupfish, sailfin molly, and mosquitofish.

- 1 Several constraints and potential impacts were considered in the design of the operational scenarios:
- 2 Water Quality Tolerances of Target Fish The fish species us ed in the ponds would have to surviv e
- and reproduce given the expected water quality conditions, both managed (salinity) and uncontrolled (air
- 4 temperature, wind m ixing, DO) conditi ons. Tilapia appear to meet many of the require ments for a
- 5 productive, sustainable fishery resource for piscivor ous birds. For some tilapia species or strains, cold
- 6 tolerance (below 13°C [55°F]) is im paired at high er salinities (Lorenzi and Schlenck, in preparation).
- 7 Hydrological modeling suggests that water tem peratures could drop below 11-13°C (52- 55°F) during
- 8 December through Februa ry. DO concentrations coul d dip below tilapia minimum toleran ces. Nutrient
- 9 concentrations are high in the New and Alamo rivers, due to contributions from agricultural runoff. Water
- quality m odeling su ggests high levels of algal growth are possible, along with oxygen deprivation
- problems that accompany hot weather algal blooms (B. Barry and M. Anderson, University of California
- Riverside, unpublished data). Also, seasonal anoxia could be more frequent and prolo nged in sprin g
- 13 (March through May) and fall (October) due to algal blooms.
- 14 **Relative Selenium Loading** Selenium in river water supplying the ponds could bioaccumulate through
- the food web from invertebrates and fish to birds (see Appendix I, Selenium Management Strategies).
- Shorter residence ti me and lower salin ity means greater inputs of river water, which would increase
- overall selenium loading to the ponds.
- 18 **Vector Risk** Mosquit oes that breed at the pond s could pose a potential hum an health risk. The
- 19 likelihood for mosquito vector impacts is based on (1) breeding season (March through November) and
- 20 (2) salinity tolerance of mosquito larvae (can survive up to 25 ppt, some reduction in populations between
- 21 25-28 ppt, < 28 ppt, reduced population 28-34 ppt, control 35 ppt).
- 22 **Emergent Vegetation Control** The SCH ponds would be managed using elevated salinity to reduce
- establishment of emergent vegetation, such as cattails and bulrush. Most vegetation is inhibited by 10 ppt
- salinity, but some strains could tolerate salinities up to 35 ppt (Table D-2).

^{1.} Relative selenium loading –shorter residence time and lower salinity means greater inputs of river water, which increases selenium loading.

Relative Selenium Loading									
	Salinity range ppt								
Residence Time	10-19	20-29	30-39	40-50					
4-8 weeks	Higher	High	Medium	Low					
10-16 weeks	High	Medium	Low	Lower					

^{2.} Vector risk of mosquitoes based on salinity tolerance (survive <28 ppt, reduced population 28-34 ppt, control 35 ppt) and breeding season (Mar-Nov).

1 D.5 Testing Operational Scenarios

- 2 Different operational scenarios would be tested in the proof-of-concept period for approximately 10 years
- 3 (estimated 2015–2025). Two or m ore operational scen arios would be im plemented si multaneously in
- 4 separate ponds, and outcomes monitored to test p erformance in meeting o bjectives and minimizing
- 5 impacts. Key indicators of i mportant phy sical, water quality, and biol ogical attributes would be
- 6 monitored.
- 7 Certain indicators of flow and water quality would be frequently monitored to guide daily or weekly pond
- 8 operations. These operational triggers include pum ping or inflow rates of river water and saline water ,
- 9 outflow rates, and salinity of water at inflow and in ponds.
- 10 Indicators of Project performance would be identified based on the SCH objectives. Thresholds or desired
- 11 conditions for each indicator would be defined, and progress toward meeting those objectives measured
- 12 according to the Monitoring and Adaptive Mana gement Fra mework (Ap pendix E). For exa mple,
- measuring abundance and community composition of fishes in different ponds would be an indicator of
- SCH Project effectiveness at providing foraging habitat for piscivorous birds (Objective 1) and creating
- sustainable aquatic habitat (Objective 3).

16 D.6 Maintenance Activities

- 17 SCH Project im plementation would also include st andard maintenance that would not be varied
- 18 experimentally. These types of operations would include:
- Sedimentation basin operations;
- Infrastructure maintenance:
- Erosion control structure maintenance;
- Vegetation control; and
- Vector control (see Appendix F, Mosquito Control Plan).

24 D.6.1 Sedimentation Basin Operations

- 25 There would be two sedimentation basi ns. Operation and maintenance would o ccur throughout the year
- and at the end of the year. One basin would be operated at any given time, storing water and settling
- sediment. The other basin would be drained of water, the sediment dried, and sediment excavated down to
- 28 original design elevation. Excavated sedi ment would be used on the Project to maintain berms, offset
- settling of berms, and create additional habitat islands if necessary.

30 D.6.2 Infrastructure Maintenance

- Monitoring of phy sical structures would be conducted on a regular basis to check condition, and and
- 32 maintenance or repairs implemented on an ongoin g basis as need ed. Project infrastructure for the water
- supply includes pumps, pump facilities and pipeli nes and inlet structures. Infrastructure for the water
- control structures includes culverts, gates, and weirs between ponds and from the ponds to the Salton Sea.

35 D.6.3 Erosion Control

- 36 Berm structure, riprap, and roadways on the crown would be checked periodically for seepage, cracking,
- 37 erosion, and extensive burrowing by animals. Areas that would potentially receive more wave action due

- 1 to extended wind fetch would receive closer scrutiny. Typical maintenance activities could include adding
- 2 riprap, filling cracks or eroded areas, or spreading gravel on the roadway.

3 D.6.4 Vegetation Control

- 4 Unwanted vegetation at SCH infrastructure could include cattails, tules and salt cedar. Measures would be
- 5 implemented to control vegetation on berms that could compromise structural integrity. Vegetation would
- 6 also be rem oved from the sedimentation basin, interception ditch, and around the river pump station to
- 7 maintain storage and flow capacity . Best management practices for vegetation control would be
- 8 implemented as appropri ate, includin g but not li mited to phy sical rem oval and chemical control
- 9 appropriate near waterways.

10 D.7 Emergency Operations

- Under certain circumstances, it may be necessary to enact rapid response operations in response to a
- sudden threat or emergency, such as:
- Avian disease outbreak;
- Rapid drawdown of ponds for emergency actions; and
- Mosquito-borne diseases (see Appendix F, Mosquito Control Plan).

16 D.7.1 Avian Disease Outbreak

- 17 Birds would be monitored regularly for signs of disease outbreaks, and monitoring would be intensified if
- signs of dise ase are present. Dead and dy ing birds would be collected to disrupt c yeles of infectious
- diseases. Potentially infectious carcasses would be incinerated at the Sonny B ono Refuge. For diseases
- that can be treated, such as the early stages of botu lism, sick birds would be collected for rehabilitation
- and release, as is currently done on the Salton Sea.

22 D.7.2 Pond Drawdown

- 23 Under certain conditions it may become necessary to rapidly reduce water elevations a pond, such as
- 24 emergency repair of water control structures or be rms, sudden change in po nd water quality, or noxious
- 25 species control. The drawdown would involve raising the flashboards on the outlet control structure(s) to
- release water to the Sea. Draining of the ponds could occur as a result of a breach in one or more berms,
- but complete draining would not be utilized as a typical pond m anagement action. Under certain
- 28 emergency conditions, such as a pesticide spill in the SCH source waters, or to eradicate a noxious
- aguatic invader, SCH ponds could be deliberately drained. In such an event, low areas o f the ponds'
- would retain water and act as tem porary refugia for fish by design, by allowing either the salvage of the
- remaining fish or leaving fish in place as recruitment stocks for re-establishing fish populations.
